# Task 1: Missing Tile

**Theorem 1.1.** Any  $2^n$  by  $2^n$  grid with one painted cell can be tiled using L-shaped triominoes such that the entire grid is covered by triominoes but no triominoes overlap with each other nor the painted cell.

## 1.1 Proof by induction.

### 1.1.1 Predicate

$P(n)$  is true when a triomino can fit into a  $2^n$  by  $2^n$  grid where once cell is painted out.

### 1.1.2 Basis Step

$P(1)$  is true because for all the possible  $2^1$  by  $2^1$  grids with a painted out cell, triominoes can tile as shown in Figure 2.1.

Figure 1.1: All possible triomino placement if a single cell was painted out

### 1.1.3 Inductive Step

Lets assume that  $P(k)$  is true for all positive interger values of  $k$ .

**Want to show** when  $P(k)$  is true, then  $P(k + 1)$  is true also. Consider a  $P(k + 1)$  grid that is subdivided into equal quadrants vertically and horizontally. Notice that each quadrant of  $P(k + 1)$  is  $P(k)$ . Then we paint out 1 cell.

Figure 1.2:  $P(k + 1)$

At this stage its not apparent if the triominoes can fill the rest of the grid. We need to somehow introduce cases made in basis step into the quadrants.

Let's paint in the middle cells, only the quadrants that haven't been painted in yet. This achieves two things, firstly this achieves placing a triminoe and secondly each quadrant now has 1 cell painted out.

Figure 1.3: Painting out the middle cells.

Since all quadrants now satisfy the conditions of  $P(k)$  which is having 1 cell painted out and we know from the basis step that every quadrant is tileable we can conclude through inductive hypothesis that  $P(k + 1)$  is true too. This completes the inductive step.

Figure 1.4: Tiling the quadrants using the basis step cases.

#### 1.1.4 Conclusion

Since we can show that when  $P(k)$  is true then  $P(k + 1)$  is true we can conclude by mathematical induction that  $P(n)$  is true for all positive integer values of  $n$ .

## Task 4: Sum Square

**Theorem 2.1.** Any  $2^n$  by  $2^n$  grid with one painted cell can be tiled using L-shaped triominoes such that the entire grid is covered by triominoes but no triominoes overlap with each other nor the painted cell.

### 2.1 Proof by induction.

#### 2.1.1 Predicate

$P(n)$  is true when a triomino can fit into a  $2^n$  by  $2^n$  grid where once cell is painted out.

#### 2.1.2 Basis Step

$P(1)$  is true because for all the possible  $2^1$  by  $2^1$  grids with a painted out cell, triominoes can tile as shown in Figure 2.1.

Figure 2.1: All possible triomino placement if a single cell was painted out

#### 2.1.3 Inductive Step

Lets assume that  $P(k)$  is true for all positive interger values of  $k$ .

**Want to show** when  $P(k)$  is true, then  $P(k + 1)$  is true also. Consider a  $P(k + 1)$  grid that is subdivided into equal quadrants vertically and horizontally. Notice that each quadrant of  $P(k + 1)$  is  $P(k)$ . Then we paint out 1 cell.

Figure 2.2:  $P(k + 1)$

At this stage its not apparent if the triominoes can fill the rest of the grid. We need to somehow introduce cases made in basis step into the quadrants.

Let's paint in the middle cells, only the quadrants that haven't been painted in yet. This achieves two things, firstly this achieves placing a triminoe and secondly each quadrant now has 1 cell painted out.

Figure 2.3: Painting out the middle cells.

Since all quadrants now satisfy the conditions of  $P(k)$  which is having 1 cell painted out and we know from the basis step that every quadrant is tileable we can conclude through inductive hypothesis that  $P(k + 1)$  is true too. This completes the inductive step.

Figure 2.4: Tiling the quadrants using the basis step cases.

#### 2.1.4 Conclusion

Since we can show that when  $P(k)$  is true then  $P(k + 1)$  is true we can conclude by mathematical induction that  $P(n)$  is true for all positive integer values of  $n$ .
